# On complex-valued solutions to a 2 D eikonal equation 

Giorgio Talenti<br>Università di Firenze, Dipartimento di Matematica,<br>viale Morgagni 67A, 50134 Firenze, Italy.<br>e-mail address: talenti@udini.math.unifi.it

1 Introduction. Let $n$ be a nonnegative sufficiently smooth function of two real variables $x$ and $y$, and let complex-valued solutions $w$ to the following first-order partial differential equation

$$
\begin{equation*}
w_{x}^{2}+w_{y}^{2}+n^{2}(x, y)=0 \tag{1.1}
\end{equation*}
$$

be in demand. Equation (1.1) arises, e.g., in questions about characteristic surfaces of Laplace's equation, and in the theory of diffraction by J.Keller and D.Ludwig. In the present paper we outline forthcoming results by R.Magnanini and the author, which include an existence theorem and a theorem about critical points.

The present section is devoted to formal remarks. Suppose

$$
\begin{equation*}
w=u+i v \tag{1.2a}
\end{equation*}
$$

i.e., suppose

$$
\begin{equation*}
u=\Re(w) \text { and } v=\Im(w) \tag{1.2b}
\end{equation*}
$$

the real and imaginary parts of $w$. Equation (1.1) is equivalent to the following firstorder system of partial differential equations

$$
\begin{align*}
& u_{x}^{2}+u_{y}^{2}+n^{2}=v_{x}^{2}+v_{y}^{2}  \tag{1.3a}\\
& u_{x} v_{x}+u_{y} v_{y}=0 \tag{1.3b}
\end{align*}
$$

- in alternative notations,

$$
\begin{aligned}
& |\nabla u|^{2}+n^{2}=|\nabla v|^{2} \\
& \nabla u \cdot \nabla v=0 .
\end{aligned}
$$

Equation (1.3a) implies that the length of the gradient of $v$ exceeds $n$, and equals $n$ exactly at the critical points of $u$. Equation (1.3b) tells us that the gradients of $u$ and $v$ are orthogonal - thus the level lines of $u$ are lines of steepest descent of $v$ and the lines of steepest descent of $u$ are level lines of $v$.

System (1.3) can be easily decoupled. In fact, algebraic manipulations show that (1.3) can be recast either in the following form

$$
\left[\begin{array}{l}
v_{x}  \tag{1.4a}\\
v_{y}
\end{array}\right]= \pm \sqrt{1+\frac{n^{2}}{u_{x}^{2}+u_{y}^{2}}}\left[\begin{array}{c}
-u_{y} \\
u_{x}
\end{array}\right]
$$

or in the form of the following pair

$$
\left[\begin{array}{l}
u_{x}  \tag{1.4b}\\
u_{y}
\end{array}\right]= \pm \sqrt{1-\frac{n^{2}}{v_{x}^{2}+v_{y}^{2}}}\left[\begin{array}{c}
v_{y} \\
-v_{x}
\end{array}\right], v_{x}^{2}+v_{y}^{2} \geq n^{2}
$$

Loosely speaking, equations (1.4a) make the gradient of $v$ available if and only if $u$ obeys the following partial differential equation

$$
\begin{equation*}
\frac{\partial}{\partial x}\left\{\sqrt{1+\frac{n^{2}}{u_{x}^{2}+u_{y}^{2}}} u_{x}\right\}+\frac{\partial}{\partial y}\left\{\sqrt{1+\frac{n^{2}}{u_{x}^{2}+u_{y}^{2}}} u_{y}\right\}=0 \tag{1.5a}
\end{equation*}
$$

the equations appearing in (1.4b) make the gradient of $u$ available if and only if $v$ obeys the constraint involved and the following partial differential equation

$$
\begin{equation*}
\frac{\partial}{\partial x}\left\{\sqrt{1-\frac{n^{2}}{v_{x}^{2}+v_{y}^{2}}} v_{x}\right\}+\frac{\partial}{\partial y}\left\{\sqrt{1-\frac{n^{2}}{v_{x}^{2}+v_{y}^{2}}} v_{y}\right\}=0 \tag{1.6a}
\end{equation*}
$$

Thus, system (1.3) is satisfied if and only if either $u$ satisfies equation (1.5a) and $v$ is given by (1.4a), or $v$ satisfies $v_{x}^{2}+v_{y}^{2} \geq n^{2}$ and equation (1.6a) and $u$ is given by (1.4b).

Equations (1.5a) and (1.6a) can be recast in the following form

$$
\begin{align*}
\left\{|\nabla u|^{4}+n^{2} u_{y}^{2}\right\} u_{x x}-2 n^{2} u_{x} u_{y} u_{x y}+\{ & \left.|\nabla u|^{4}+n^{2} u_{x}^{2}\right\} u_{y y}  \tag{1.5b}\\
& +n|\nabla u|^{2} \nabla n \cdot \nabla u=0
\end{align*}
$$

and

$$
\begin{align*}
&\left\{|\nabla v|^{4}-n^{2} v_{y}^{2}\right\} v_{x x}+2 n^{2} v_{x} v_{y} v_{x y}+\left\{|\nabla v|^{4}-n^{2} v_{x}^{2}\right\} v_{y y} \\
&-n|\nabla v|^{2} \nabla n \cdot \nabla v=0 \tag{1.6b}
\end{align*}
$$

respectively - i.e., in the form of semilinear second-order partial differential equations with polynomial nonlinearities. If the coefficients of $u_{x x}, u_{x y}, u_{y y}$ appearing on the lefthand side of (1.5b) are denoted by $a, 2 b, c$, then

$$
\left|\begin{array}{ll}
a & b \\
b & c
\end{array}\right|=|\nabla u|^{6}\left(|\nabla u|^{2}+n^{2}\right) \geq 0 .
$$

Hence equation (1.5b) should be qualified elliptic or elliptic-parabolic - notice that degeneracies occur at the critical points of solutions. If $a, 2 b, c$ denote the coefficients of $v_{x x}, v_{x y}, v_{y y}$ appearing on the left-hand side of $(1.6 \mathrm{~b})$, then

$$
\left|\begin{array}{ll}
a & b \\
b & c
\end{array}\right|=|\nabla v|^{6}\left(|\nabla v|^{2}-n^{2}\right) .
$$

Hence solutions $v$ to (1.6b), such that $|\nabla v|^{2}>n^{2}$, are elliptic; any real-valued solution $v$ to the equation

$$
|\nabla v|^{2}=n^{2}
$$

- the standard equation of geometrical optics, which implies equation (1.6c) indeed is a parabolic solution to (1.6c).

Observe that a set of terms, appearing on the left-hand side of equations (1.5b) and (1.6b), has a special geometric meaning. In fact, equations (1.5b) and (1.6b) read

$$
\begin{equation*}
|\nabla u| \Delta u+n^{2} h+n \nabla n \cdot \frac{\nabla u}{|\nabla u|}=0 \tag{1.5c}
\end{equation*}
$$

and

$$
\begin{equation*}
|\nabla v| \Delta v-n^{2} k-n \nabla n \cdot \frac{\nabla v}{|\nabla v|}=0 \tag{1.6c}
\end{equation*}
$$

respectively. Here

$$
\begin{align*}
& h=\operatorname{div} \frac{\nabla u}{|\nabla u|}=\left(u_{x}^{2}+u_{y}^{2}\right)^{-3 / 2}\left(u_{y}^{2} u_{x x}-2 u_{y} u_{x} u_{x y}+u_{x}^{2} u_{y y}\right),  \tag{1.7a}\\
& k=\operatorname{div} \frac{\nabla v}{|\nabla v|} . \tag{1.8a}
\end{align*}
$$

Recall from differential geometry that the absolute value of $h$ at a point $(x, y)$, where the gradient of $u$ does not vanish, is the curvature at $(x, y)$ of the level line of $u$ crossing $(x, y)$; the absolute value of $k$ at a point $(x, y)$ is the curvature at $(x, y)$ of the level line of $v$ crossing $(x, y)$. Equations (1.4) yield

$$
\begin{align*}
& \pm h=\operatorname{div} \frac{1}{|\nabla v|}\left[\begin{array}{c}
v_{y} \\
-v_{x}
\end{array}\right]=\left(v_{x}^{2}+v_{y}^{2}\right)^{-3 / 2}\left\{-v_{x} v_{y}\left(v_{x x}-v_{y y}\right)+\left(v_{x}^{2}-v_{y}^{2}\right) v_{x y}\right\}  \tag{1.7b}\\
& \pm k=\operatorname{div} \frac{1}{|\nabla u|}\left[\begin{array}{c}
-u_{y} \\
u_{x}
\end{array}\right] \tag{1.8b}
\end{align*}
$$

hence the absolute value of $h$ at a point $(x, y)$ is also the curvature at $(x, y)$ of the line of steepest descent of $v$ crossing $(x, y)$, and the absolute value of $k$ at a point $(x, y)$ is also the curvature at $(x, y)$ of the line of steepest descent of $u$ crossing $(x, y)$.

2 An existence theorem. The existence of solutions to equation (1.5b), that take prescribed boundary values, can be settled in the following way.

Theorem 1. Let $G$ be an open subset of the euclidean plane, having finite area - the ground domain; let $g$ be a real-valued function from Sobolev space $W^{1,2}(G)$ - the boundary datum. Suppose $n$ is bounded and belongs to $W^{1,2}(G)$. Then a real-valued function $u$ exists such that: (i) $u$ is in $W^{1,2}(G), u$ has second-order generalized derivatives and satisfies

$$
\begin{align*}
& \int_{G(\delta)} \frac{|\nabla u|^{2}}{n^{2}+|\nabla u|^{2}}\left(u_{x x}^{2}+2 u_{x y}^{2}+u_{y y}^{2}\right) d x d y \leq  \tag{2.1}\\
& \delta^{-2} \int_{G}\left(n^{2}+|\nabla u|^{2}\right) d x d y+\int_{G}|\nabla n|^{2} d x d y
\end{align*}
$$

for every positive $\delta$ - here $G(\delta)=\{(x, y) \in G$ : $\operatorname{dist}((x, y), \partial G)>\delta\}$; (ii) $u$ satisfies equation (1.5b) almost everywhere in $G, u$ is a viscosity solution to (1.5b); (iii) $u$ fits $g$ on $\partial G$, i.e., $u-g \in W_{0}^{1,2}(G)$.

Proof, outlined. Let

$$
\begin{equation*}
j(x, y ; \rho)=\int_{0}^{\rho} \sqrt{n^{2}(x, y)+t^{2}} d t \tag{2.2a}
\end{equation*}
$$

and let a functional $J_{\varepsilon}$ be defined by

$$
\begin{equation*}
J_{\varepsilon}(u)=\int_{G} j\left(x, y ; \sqrt{\varepsilon^{2}+|\nabla u|^{2}}\right) d x d y \tag{2.2~b}
\end{equation*}
$$

for every nonnegative $\varepsilon$. Formulas (2.2) guarantee that $J_{\varepsilon}$ is strictly convex and coercive, i.e., satisfies

$$
J_{\varepsilon}(u) \geq \frac{1}{2} \int_{G}|\nabla u|^{2} d x d y
$$

for every $u$ from $W^{1,2}(G)$. Consequently, the following variational problem

$$
\begin{align*}
& J_{\varepsilon}(u)=\text { minimum }  \tag{2.3}\\
& \text { under the condition: } u-g \in W_{0}^{1,2}(G)
\end{align*}
$$

has a unique solution - call it $u_{\varepsilon}$.
Observe that equation (1.5a) is exactly the Euler equation of functional $J_{0}$. However, $u_{0}$ need not satisfy such an equation. In fact, the following expansion

$$
j(x, y, \rho)=n(x, y) \rho\left\{1+n^{-2}(x, y) \rho^{2}+\cdots\right\}
$$

which holds for sufficiently small $\rho$, shows that $J_{0}$ is not differentiable at any function having critical points.

The main ingredient of the proof are statements (i)-(iii) below.
(i) If $\varepsilon>0, J_{\varepsilon}$ is smoothly differentiable; moreover, $u_{\varepsilon}$ satisfy the relevant Euler equation both in the following weak form

$$
\begin{equation*}
\frac{\partial}{\partial x}\left\{\sqrt{1+\frac{n^{2}}{|\nabla u|^{2}+\varepsilon^{2}}} \frac{\partial u_{\varepsilon}}{\partial x}\right\}+\frac{\partial}{\partial y}\left\{\sqrt{1+\frac{n^{2}}{|\nabla u|^{2}+\varepsilon^{2}}} \frac{\partial u_{\varepsilon}}{\partial y}\right\}=0 \tag{2.4a}
\end{equation*}
$$

and in the following stronger form

$$
\begin{gather*}
\varepsilon^{2}\left(n^{2}+2|\nabla u|^{2}+\varepsilon^{2}\right) \Delta u+  \tag{2.4~b}\\
\left\{\left|\nabla u_{\varepsilon}\right|^{4}+n^{2}\left(\frac{\partial u_{\varepsilon}}{\partial y}\right)^{2}\right\} \frac{\partial^{2} u_{\varepsilon}}{\partial x^{2}}-2 n^{2} \frac{\partial u_{\varepsilon}}{\partial y} \frac{\partial u_{\varepsilon}}{\partial x} \frac{\partial^{2} u_{\varepsilon}}{\partial x \partial y}+\left\{\left|\nabla u_{\varepsilon}\right|^{4}+n^{2}\left(\frac{\partial u_{\varepsilon}}{\partial x}\right)^{2}\right\} \frac{\partial^{2} u_{\varepsilon}}{\partial y^{2}}+ \\
n\left(|\nabla u|^{2}+\varepsilon^{2}\right) \nabla n \cdot \nabla u=0
\end{gather*}
$$

- in particular, $u_{\varepsilon}$ has locally square-integrable second-order partial derivatives.
(ii) If $\varepsilon>0, u_{\varepsilon}$ satisfies the following inequality

$$
\begin{align*}
\int_{G(\delta)} \frac{\left|\nabla u_{\varepsilon}\right|^{2}}{n^{2}+\left|\nabla u_{\varepsilon}\right|^{2}}\left\{\left(\frac{\partial^{2} u_{\varepsilon}}{\partial x^{2}}\right)^{2}+2\left(\frac{\partial^{2} u_{\varepsilon}}{\partial x \partial y}\right)^{2}+\left(\frac{\partial^{2} u_{\varepsilon}}{\partial y^{2}}\right)^{2}\right\} d x d y \leq  \tag{2.5}\\
\delta^{-2} \int_{G}\left(n^{2}+\left|\nabla u_{\varepsilon}\right|^{2}\right) d x d y+\int_{G}|\nabla n|^{2} d x d y
\end{align*}
$$

for every positive $\delta$ - observe that the constants involved in inequality (2.5) are independent of $\varepsilon$.
(iii) $J_{\varepsilon}$ converges uniformly to $J_{0}$ as $\varepsilon \downarrow 0$, more precisely

$$
\begin{equation*}
0 \leq J_{\varepsilon}(u)-J_{0}(u) \leq \int_{G} j(x, y ; \varepsilon) d x d y \tag{2.6}
\end{equation*}
$$

for every $u$ in $W^{1,2}(G)$.
Statements (i)-(iii) allows one to infer that $u_{\varepsilon}$ converge to $u$ - in a topology stronger than the topology of $W^{1,2}(G)$ and the topology of any $W_{l o c}^{1, p}(G)$ - as $\varepsilon$ goes to zero, and that $u_{0}$ is the sought solution $u$.

3 Critical points. As a rule, the critical points of solutions to second-order 2D partial differential equations are isolated. The following theorem shows that equation (1.5b) has the opposite property.

Theorem 2. Suppose

$$
\begin{equation*}
n(x, y) \geq \text { Constant }>0 \tag{3.1}
\end{equation*}
$$

Let $w$ be a smooth solution to equation (1.1), and let $u$ be the real part of $w$. Then $u$ cannot have isolated critical points.

Proof. Let

$$
\boldsymbol{l}=\frac{1}{|\nabla u|}\left[\begin{array}{c}
-u_{y}  \tag{3.2a}\\
u_{x}
\end{array}\right]
$$

a unit vector field whose trajectories are the level lines of $u$ and whose divergence is in absolute value - the curvature of the lines of steepest descent of $u$. Equation (3.2a) gives

$$
\left[\begin{array}{cc}
0 & 1  \tag{3.2b}\\
-1 & 0
\end{array}\right] \boldsymbol{l}=\frac{\nabla u}{|\nabla u|},
$$

a unit vector field whose trajectories are the lines of steepest descent of $u$ and whose divergence is - in absolute value - the curvature of the level lines of $u$.

Crucially, equations (1.4) and (3.2), and hypothesis (3.1) imply that $l$ is smooth everywhere, even across the critical points of $u$.

As a consequence, the level lines of $u$ are free from singular points, and the lines of steepest descent have a smooth curvature. Since

$$
\nabla|\nabla u|=\left[\begin{array}{cc}
u_{x x} & u_{x y}  \tag{3.3}\\
u_{x y} & u_{y y}
\end{array}\right] \frac{\nabla u}{|\nabla u|}
$$

we infer also that $|\nabla u|$ is continuously differentiable everywhere, even near the critical points of $u$.

An inspection shows that

$$
\begin{equation*}
\frac{\partial}{\partial l}|\nabla u|+(\operatorname{div} l)|\nabla u|=0 . \tag{3.4}
\end{equation*}
$$

In conclusion, if $u$ has a critical point - the origin, say - then the critical points of $u$ must spread along the level line of $u$ which crosses the origin.
